

Phishing Analysis Report

Project: Email Risk Analyzer

1. Objective

Analyze raw email headers and body text to identify common phishing indicators, spoofing signs, authentication failures, suspicious links, and urgent action language.

2. Sample Email Analysis

Indicator	Observation	Risk Contribution
From / Return-Path	Different domains detected	+25
SPF	SPF authentication failed	+20
DKIM	DKIM authentication failed	+20
Link	External verification link detected	+10
Urgency	Suspended / verify / password / immediately	+20
Final score	Risk score capped at 100	95/100
Risk level	High	Phishing indicators present

3. Findings

The sample contains several signals associated with phishing: a mismatch between From and Return-Path domains, failed SPF and DKIM checks, an external verification URL, and language designed to create urgency. These indicators produce a high calculated risk score in the demonstration script.

4. Recommended User Action

Do not enter passwords or sensitive information through suspicious links. Verify the message using an independently known official contact or website. Treat the report as an automated screening result, not a definitive determination that an email is malicious.

5. Scope and Safety

The demonstration uses synthetic metadata and reserved example domains. It does not access real accounts, send messages, or visit live links.
